

The role of expectancy and pharmacology in alcohol related behaviour.

Dr Abigail Rose
Rebekah Robson
November 2009

Expectancy theory

Two models: **placebo effect** and **compensatory response**

Research

- Balanced placebo design has been used extensively
Marlett et al. (1973)
- Current research shows instruction can be more important in determining alcohol's effects in dependent and non-dependent drinkers
- Aim: use balanced placebo design to find roles of expectancy vs pharmacology in alcohol related impairment in bingers and non-bingers.

Method

- Within subjects balanced placebo design with four conditions
- Participants – some couldn't be used

Measurements and Tasks

- Alcohol Expectancy Questionnaire (Fromme et al. 1993)
- Temptation & Restraint Inventory (Collins and Lapp 1992)
- Mood visual analogue scale (Duka et al. 1998)
- Immediate & Delayed Memory Task (Dougherty and Marsh 2003)
- Go-stop paradigm (Dougherty et al. 2003)

IMT

Procedure

Baseline

AUseQ, AEQ, TRI
Mood VAS

Drinks & Instruction

TAGA TSGS TAGP TSGA

- Men: 0.6g/kg Women: 0.5 g/kg

Tasks & Measures

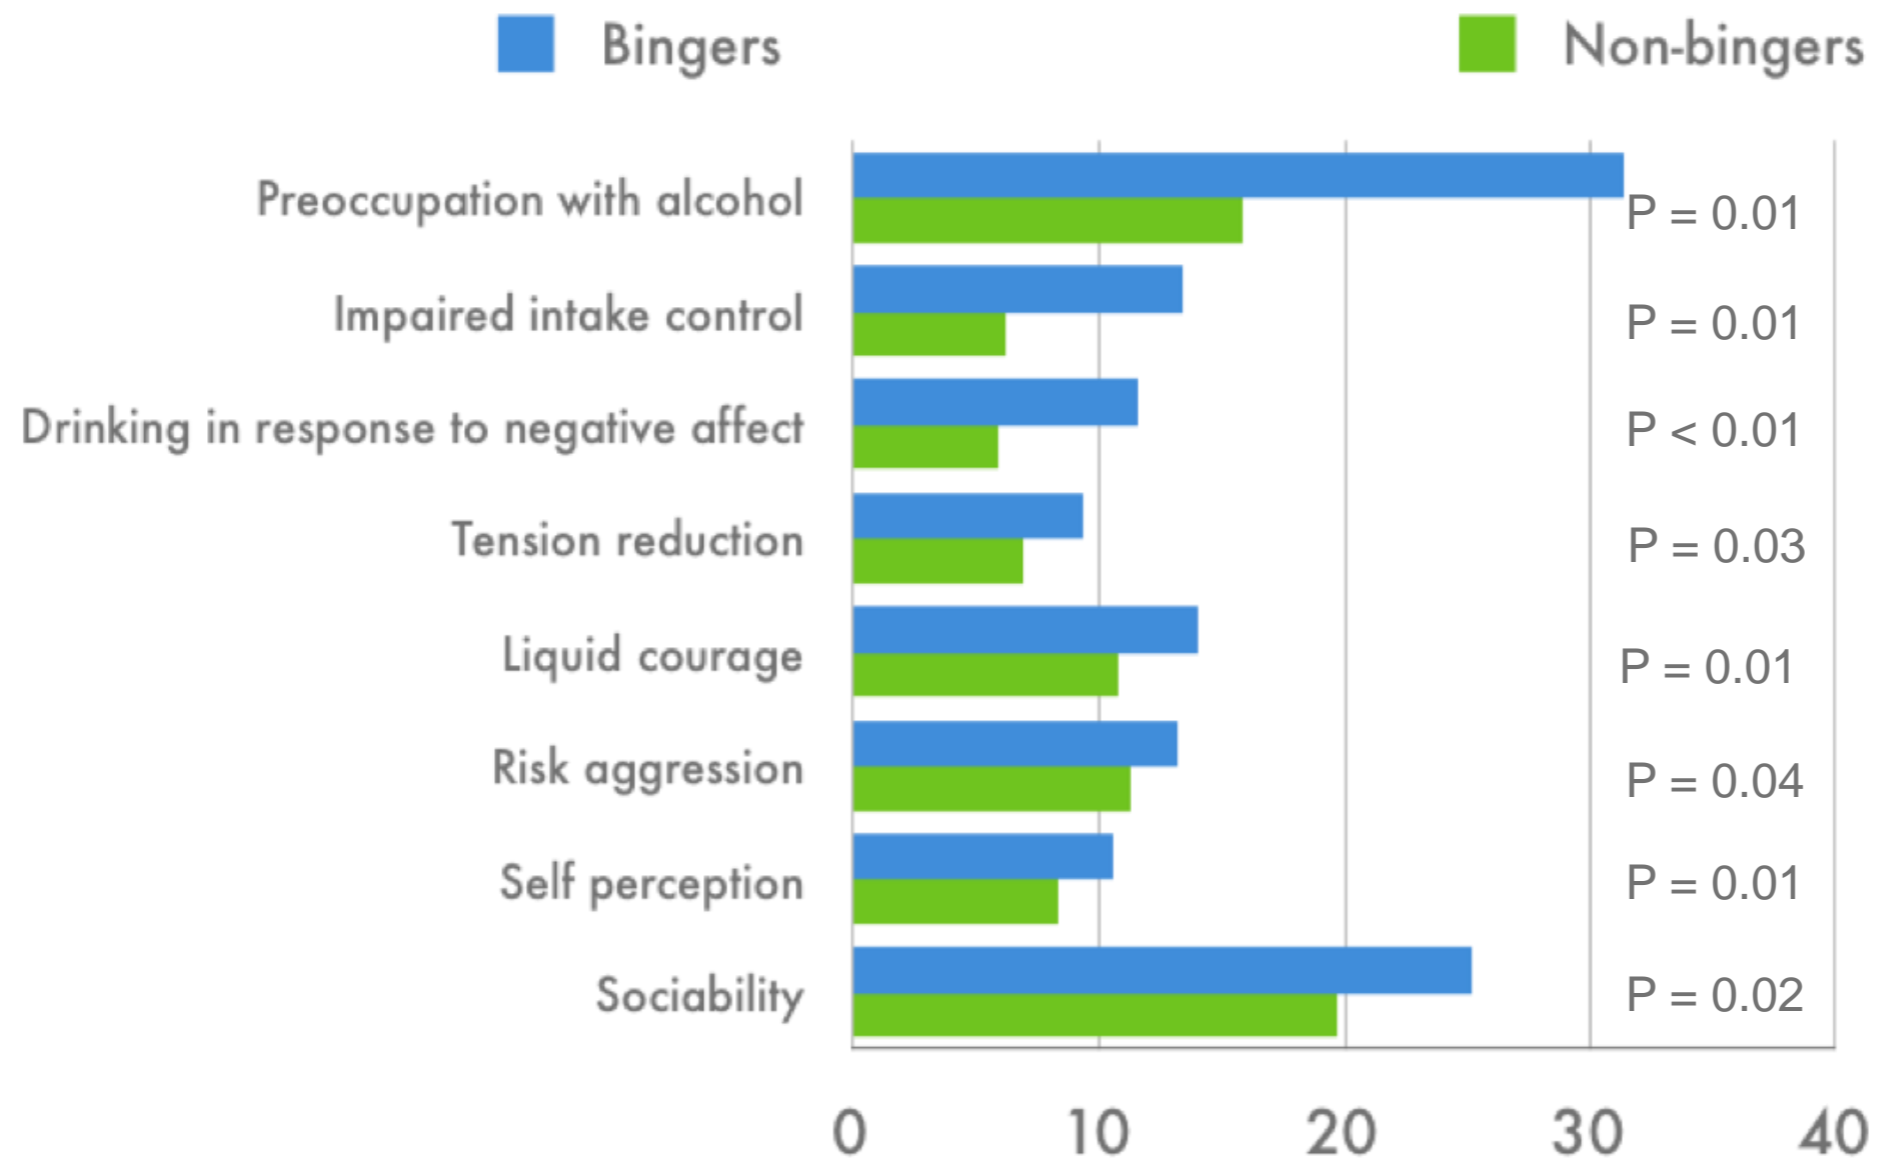

IMT, DMT, GNG
(counterbalanced)
Mood VAS,
(post task)

Mood VAS
(post drink)

Results

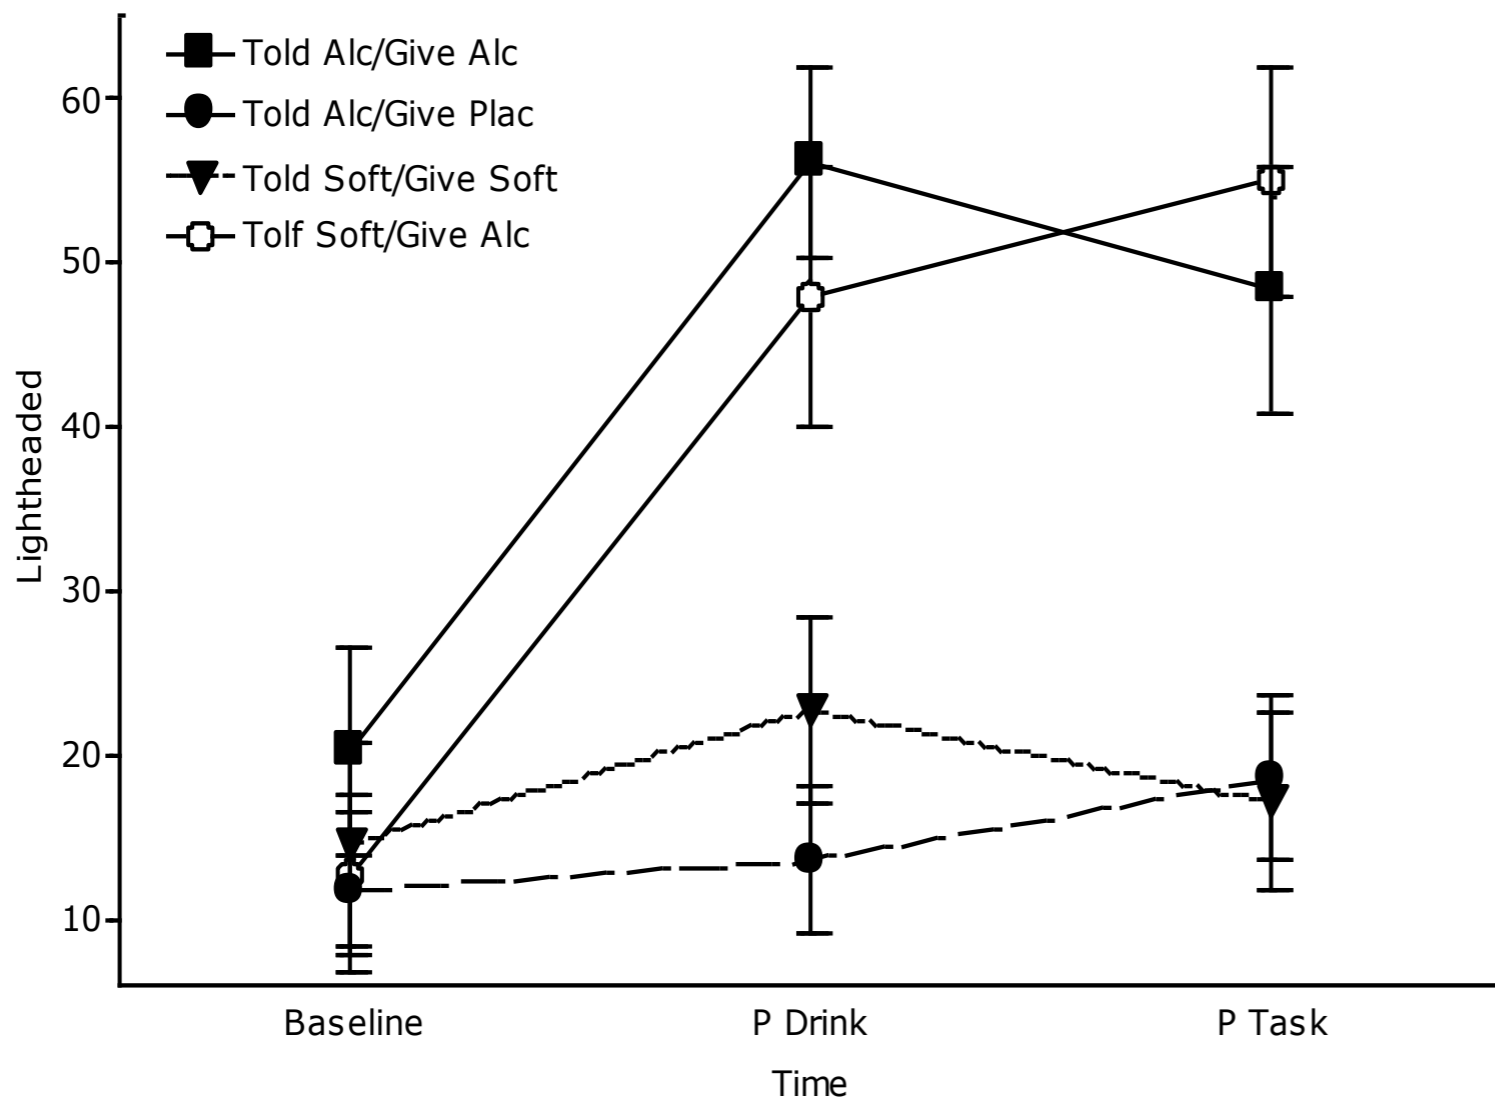

TRI and AEQ

Pre-clinical
stage of
dependence?

Results

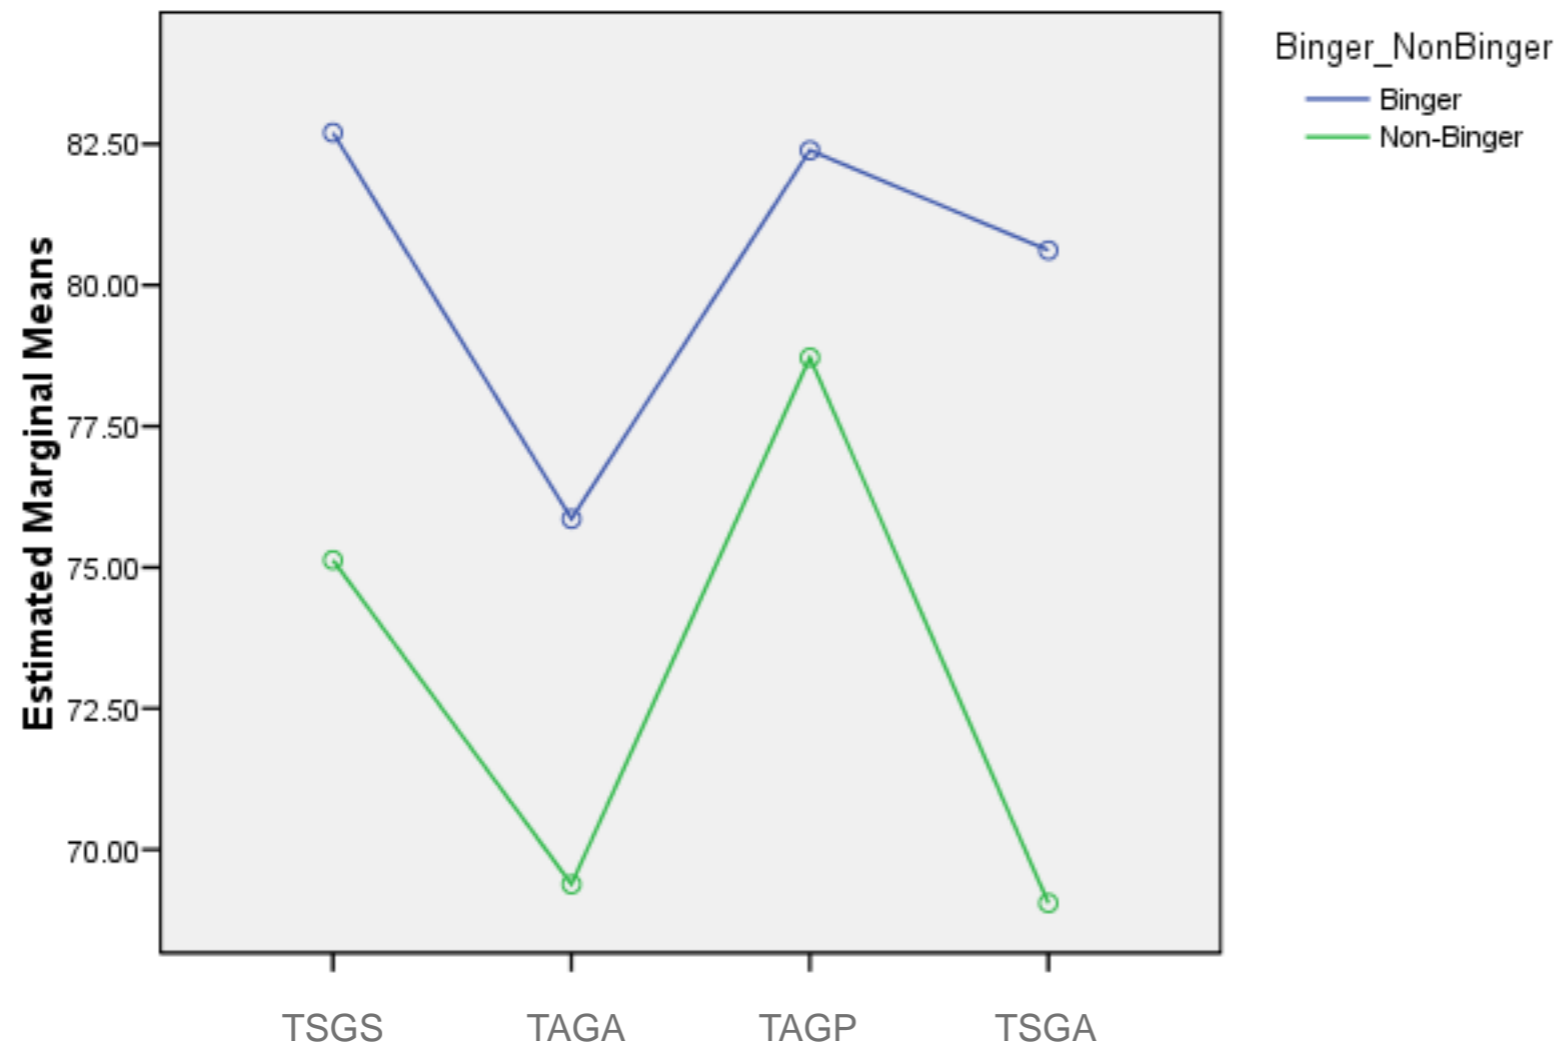

Lightheadedness

Subtraction analysis showed that non-binge drinkers were more lightheaded in the given alcohol conditions; binge drinkers did not show this effect of alcohol on lightheadedness ($p=0.03$)

Results

IMT correct responses

Alcohol consumption (men: 0.6g/kg, women: 0.5g/kg) decreased correct responding on the IMT ($p=0.011$)

Results

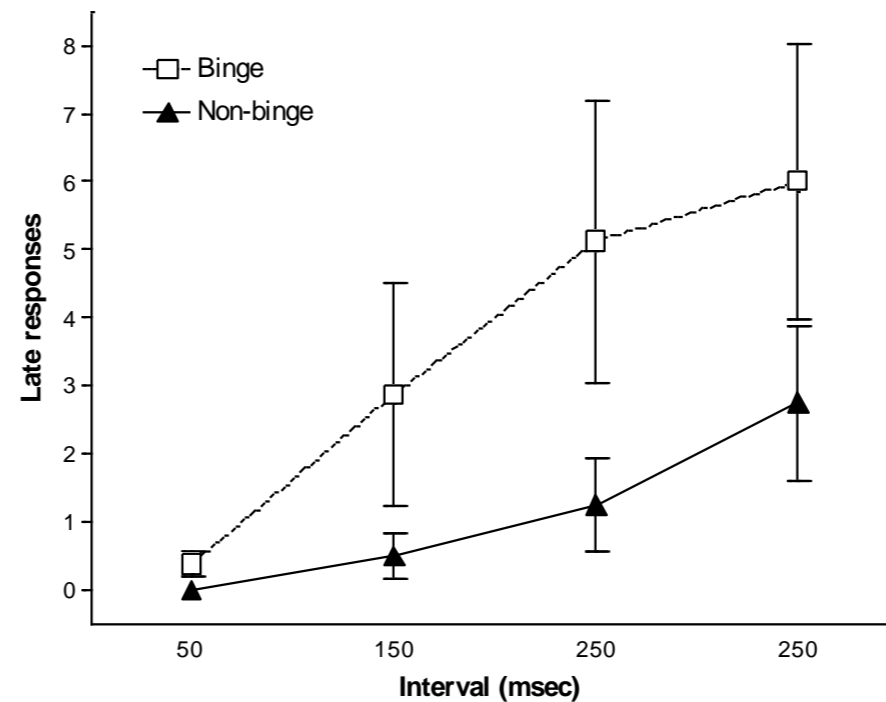

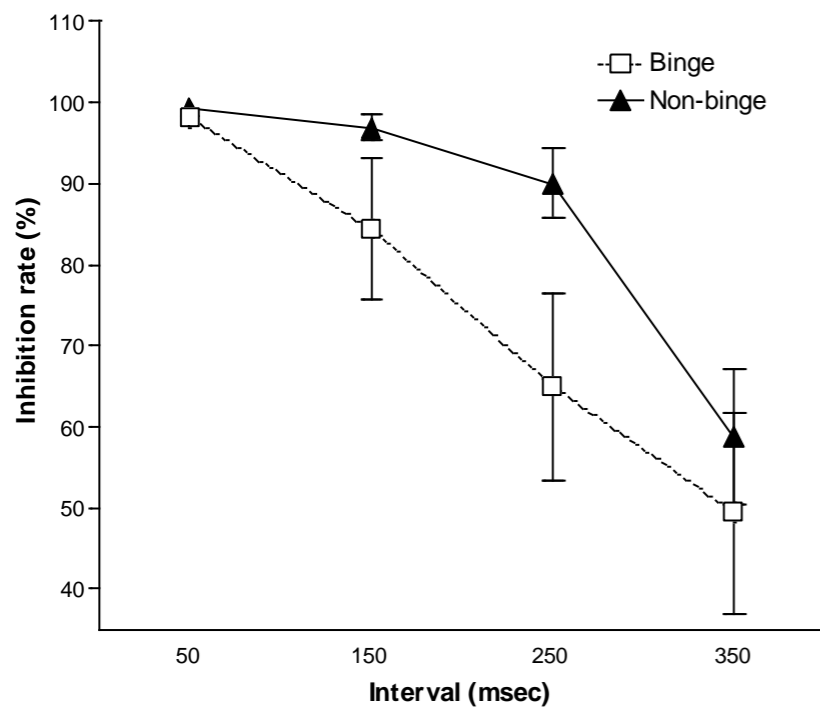

DMT correct responses

Binge drinkers made more correct responses in TSGS relative to TAGP condition. This was reversed in non-binge drinkers ($p=0.03$)

Results

Go-stop paradigm

Behavioural inhibition on the GSP was greatest in the told alcohol/given soft drink condition ($p < 0.01$) and bingers made most errors ($p = 0.04$).

Bingers are worse no matter what the condition. Bingers were more impulsive.

Summary

- **Non-bingers:**
 - Alcohol instruction led to some performance improvement (compensatory model)
- **Bingers:**
 - at risk of alcohol dependence.
 - alcohol instruction impaired performance as per placebo model.
 - Binge drinkers tolerant to alcohol's discriminative properties.

Conclusion

- Challenging binge drinker expectations may reduce aversive effects of alcohol in this group.
- Different models between groups:
 - Predisposition?
 - Result of excessive drinking?
